1. Spectrogram/MFCC features convert raw audio into frequency-based patterns that are easier for the model to process and recognize.
2. The representative dataset determines the correct scaling ranges during quantization so the INT8 model can maintain accuracy.
3. `audio_processor.get_data()` retrieves batches of processed audio features and their labels for training or testing the model.
4. `g_model` stores the TensorFlow Lite model data and `g_model_len` stores the model size so the Arduino can correctly load the embedded model into memory.

5.
